"Day 4 - Dynamic Frontend Components - [Shop.Co by MZ]"

To create dynamic routes for product pages, I set up a file structure in Next.js with /pages/products/[slug].tsx to handle product-specific routes. I utilized getStaticProps to fetch product data from Sanity based on the dynamic slug parameter. This data is then passed to the component to render the relevant product details. Finally, the product slug is used within links and the page content to dynamically display each product's information.

```

       aitignore
                                                           src={product.imageUrl}
                                                           width={400}
height={400}
                                                            alt={product.title}
className="rounded-lg shadow-md object-cover
```

Here are some examples:

To set up a search bar with suggestions appearing after the first character, I used an input field where the value is bound to the searchTerm state. The useEffect hook listens for changes in the searchTerm and triggers a query to fetch products based on the input. The query is executed as soon as the user starts typing (with no character limit). Suggestions are displayed in a dropdown under the input field, showing relevant product names. I used Sanity's query language to fetch product data and filter it dynamically based on the input.
